Air Motors, Series P1V-A

P1V-A is a range of reversible air motors intended for heavy and demanding applications. The motor housings are made from painted cast iron, and the components sealed to permit operation in damp and dirty environments.

The range contains three different sizes, P1V-A160, P1V-A260 and P1V-A360, with power ratings of 1600, 2600 or 3600 Watts. The basic motors can be supplied with built-in gearboxes, either planetary, helical or worm drive, to provide the correct speed of rotation and torque, and the correct installation mountings.

Basic motor

All pneumatic motors are equipped with spring loaded vanes as standard, which gives the motors very good starting and low speed running characteristics. They are also equipped with vanes for intermittent lube-free operation as standard. 100% lubrication-free vanes are obtainable as options. The simple construction of the motors makes them very reliable, with long service life and they are easy to service.

Motors with planetary gears

A P1V-A combined with a planetary gear has small installation dimensions, low weight in relation to performance, free installation position, flange mounting as standard, in line output shaft and high efficiency. They are available with shaft speeds ranging from 95 rpm to 1200 rpm, with torques ranging from 16 Nm to 160 Nm.

Motors with helical gears

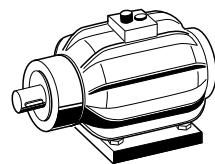

A P1V-A combined with a helical gear has high efficiency, simple installation with flange or foot, and competitive pricing. They are available with shaft speeds ranging from 25 rpm to 1050 rpm, with torques ranging from 23 Nm to 1800 Nm. Oil-bath gears mean that the installation position must be decided beforehand. The installation position governs the amount of oil in the gear and the location of filling and drain plugs.

Motors with worm gears

A P1V-A combined with a worm drive gear has the following characteristics: gearboxes with high gear ratios are self-locking, which means that they can be used to maintain the output shaft in position, simple installation with the flange on the left or right sides or with a foot, small installation dimensions and competitive pricing. They are available with shaft speeds ranging from 62 rpm to 500 rpm, with torques ranging from 38 Nm to 670 Nm. Oil-bath gears mean that the installation position must be decided beforehand. The installation position governs the amount of oil in the gear and the location of filling and drain plugs.

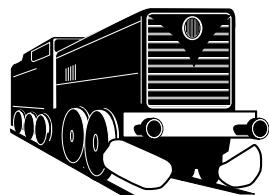

Products specially designed for
mobile applications

Air motors have much smaller installation dimensions than corresponding electric motors.

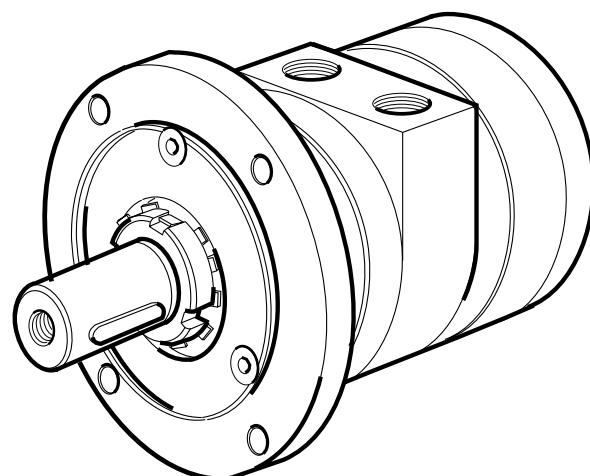

Air motors can be stopped and started continually without damage.

Air motors can be loaded until they stall, without damage. They are designed to be able to withstand the toughest heat, vibration, impact etc.

The simple design principle of air motors make them very easy to service.

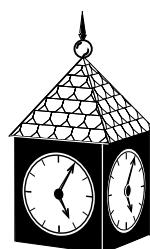

The weight of an air motor is several times less than corresponding electric motors.

The motors are reversible as standard.

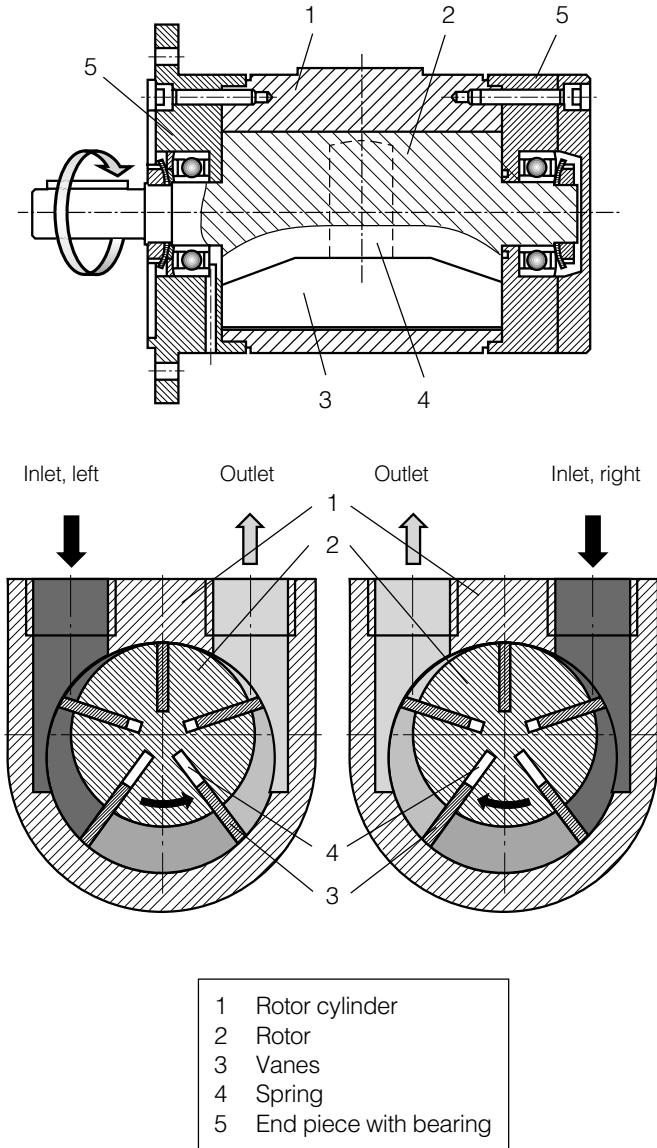

Air motors can be used in the harshest environments.

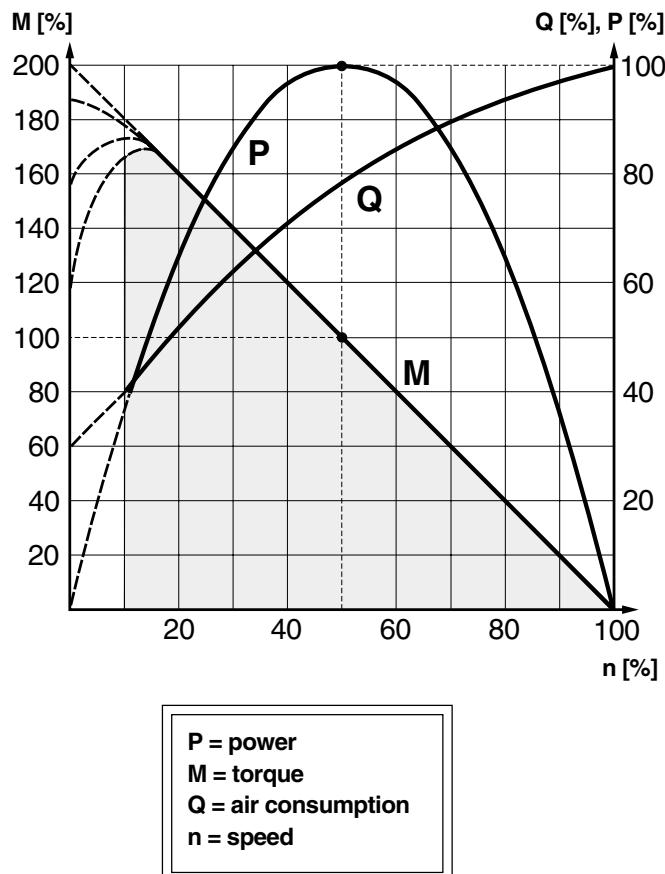

The reliability of air motors is very high, thanks to the design and the low number of moving parts.

Principles of air motor function

Torque, power and air consumption graphs

The performance characteristics of each motor are shown in a family of curves as above, from which torque, power and air consumption can be read off as a function of speed. Power is zero when the motor is stationary and also when running at free speed (100%) with no load. Maximum power (100%) is normally developed when the motor is driving a load at approximately half the free speed (50%).

Torque at free speed is zero, but increases as soon as a load is applied, rising linearly until the motor stalls. As the motor can then stop with the vanes in various positions, it is not possible to specify an exact torque. However, a minimum starting torque is shown in all tables.

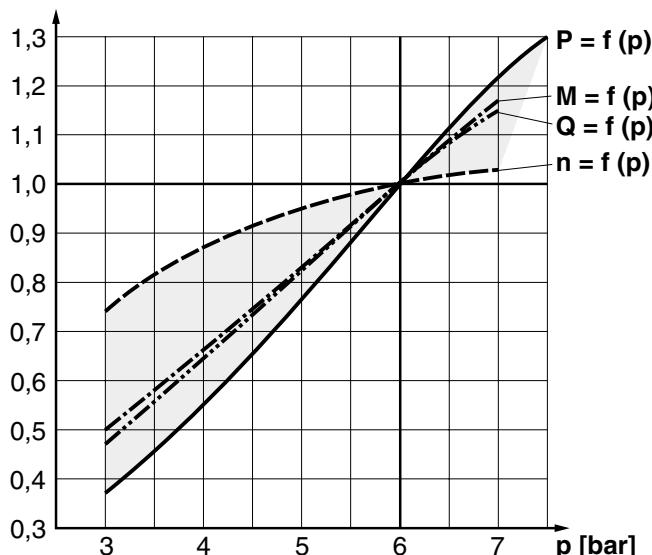

Air consumption is greatest at free speed, and decreases with decreasing speed, as shown in the above diagram.

There are a number of designs of air motor. Parker Pneumatic has chosen to use the vane rotor design, because of its simple design and reliable operation. The small external dimensions of vane motors make them suitable for all applications.

The principle of the vane motor is that a rotor with a number of vanes is enclosed in a rotor cylinder. The motor is supplied with compressed air through one connection and air escapes from the other connection. To give reliable starting, the springs press the vanes against the rotor cylinder. The air pressure always bears at right angles against a surface. This means that the torque of the motor is a result of the vane surfaces and the air pressure.

Correction diagrams

Correction factor

P = power
M = torque
Q = air consumption
n = speed

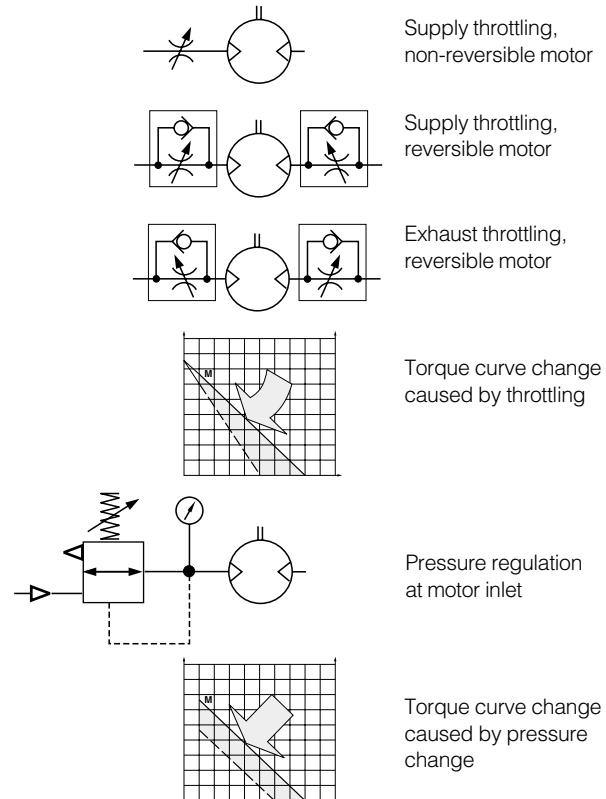

All catalogue data and curves are specified at a supply pressure of 6 bar to the motor. This diagram shows the effect of pressure on speed, specified torque, power and air consumption.

Start off on the curve at the pressure used and then look up to the lines for power, torque and air consumption. Read off the correction factor on the Y axis for each curve and multiply this by the specified catalogue data in the table, or data read from the torque and power graphs.

Example: at 4 bar supply pressure, the power is only $0.55 \times$ power at 6 bar supply pressure.

This example shows how strongly power falls if supply pressure is reduced. You must therefore ensure that the motor is supplied through pipes of sufficient diameter to avoid pressure drop.

Speed regulation

Throttling

The most common way to reduce the speed of a motor is to install a flow control valve in the air inlet. When the motor is used in applications where it must reverse and it is necessary to restrict the speed in both directions, flow control valves with by-pass should be used in both directions.

Inlet throttling

If the inlet air is restricted, the air supply is restricted and the free speed of the motor falls, but there is full pressure on the vanes at low speeds. This means that we get full torque from the motor at low speeds despite the low air flow.

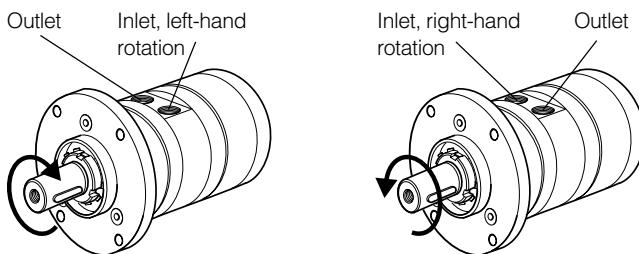

Since the torque curve becomes "steeper", this also means that we get a lower torque at any given speed than would be developed at full air flow.

Pressure regulation

The speed and torque can also be regulated by installing a pressure regulator in the inlet pipe. This means that the motor is constantly supplied with air at lower pressure, which means that when the motor is braked, it develops a lower torque on the output shaft.

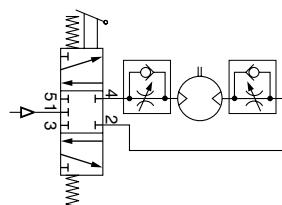

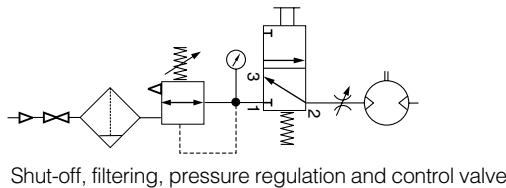

In brief: Inlet throttling gives reduced speed in one direction but maintains torque when braked. The torque curve becomes steeper. Pressure regulation in the inlet cuts torque when the motor is braked, and also reduces speed. The torque curve is moved parallel.

Direction of motor rotation

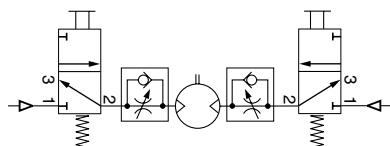

The direction of rotation of reversible motors is obtained by supplying inlet L or inlet R with compressed air. The motor can be stopped and started continually without damage occurring.

Air supply

Reversible motor with 5/3 control valve

Reversible motor with two 3/2 control valves

The air with which the motor is supplied must be filtered and regulated. Directional valves are needed to provide it with air, to get the motor to rotate when we want it to. These valves can be equipped with several means of actuation, such as electric, manual and pneumatic control. When the motor is used in a non-reversible application, it is sufficient to use a 2/2 or 3/2 valve for supply. Either one 5/3 or two 3/2 valves are needed for a reversible motor, to ensure that the motor receives compressed air and the residual air outlet is vented. A flow control valve can be installed in the supply pipe to regulate the motor speed if the motor is not used as a reversible motor. One flow control valve with by-pass is needed to regulate each direction of rotation if the motor is used as a reversible motor. The built-in check valve will then allow air from the residual air outlet to escape through the outlet port in the control valve.

The compressed air supply must have sufficiently large pipes and valves to give the motor maximum power. The motor needs 6 bar at the supply port all the time. A reduction of pressure to 5 bar reduces the power developed to 77%, and to 55% at 4 bar.

Choice of components for air supply

Since the supply pressure at the air motor inlet port is of considerable importance for obtaining the power, speed and torque quoted in the catalogue, the recommendations below should be observed.

The following data must be complied with:

Supply pressure: 7 bar

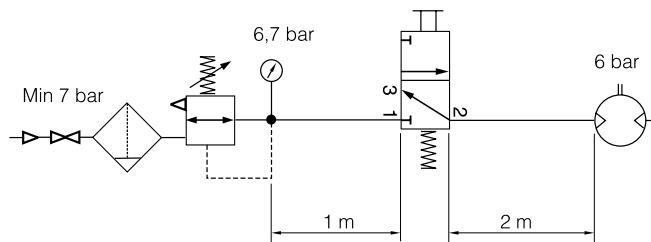

Regulator pressure setting: 6.7 bar

Pipe length between air treatment unit and valve: max. 1 m

Pipe length valve and air motor: max. 2 m

The pressure drop through the air preparation unit, pipe, valve and pipe means that 6 bar pressure is obtained at the motor supply port.

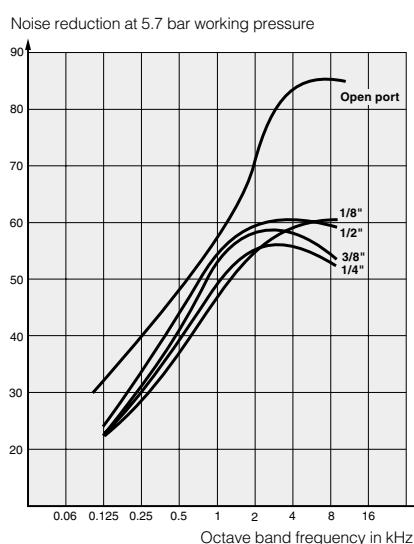

Please refer to the correction diagram on page 7, which shows what lower supply pressure means for power, speed and torque.

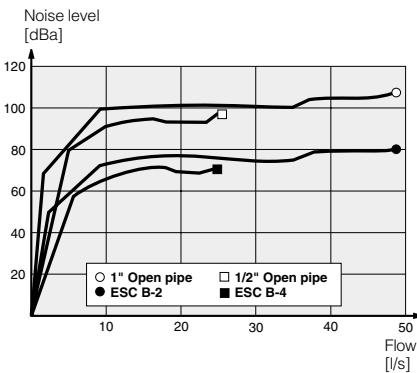

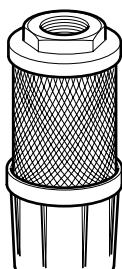

Air motor	P1V-A160	P1V-A260	P1V-A360
Air flow required, Nl/s	32	60	80
Min pipe ID, inlet, mm	19	19	22
Min pipe ID, outlet, mm	19	25	32

Recommended valve series			
Valves with connections in valve housing			
VE42/43			
VE82/83			
Valves with connections in base plate			
Apollo, size 3			
Flexflow VG45			
Flexflow VE45			

Silencing

Exhaust silencer

Central silencer

The noise from a air motor consists of both mechanical noise and a pulsating noise from the air flowing out of the outlet. The installation of the motor has a considerable effect on mechanical noise. It should be installed so that no mechanical resonance effects can occur. The outlet air creates a noise level which can amount to 115 dB(A) if the air is allowed to exhaust freely into the atmosphere. Various types of exhaust silencers are used to reduce this level. The most common type screws directly onto the exhaust port of the motor. Since the motor function causes the exhaust air to pulsate, it is a good idea to allow the air to exhaust into some kind of chamber first, which reduces the pulsations before they reach the silencer. The device which gives best silencing is to connect a soft plastic hose to a large central silencer which has the largest possible area, to reduce the speed of the out-flowing air as far as possible.

NOTE! Remember that a silencer which is too small or is blocked, generates back pressure on the outlet side of the motor, which reduces the motor power.

Lubrication and service life

Oil and oil mist are things which one tries to avoid to get the best possible working environment. In addition, purchasing, installation and maintenance of oil mist equipment costs money and, above all, time to achieve optimum lubrication effect. Users in all industries now try to avoid using components which have to be lubricated.

The P1V-A motor is equipped with vanes for intermittent operation as standard, which is the most common application of air motors. The motor is also available with optional hard vanes for continuous lubrication-free operation (option "C").

Expected service life of P1V-A motors

Air treatment

Filtering	40 µm or better
Dew point	+3 to +4 °C
Air temperature	+20°C

Intermittent lubrication-free operation of P1V-A standard motors

Duty cycle	70%
Max. duration of intermittent use	15 minutes
Filtering 40 µm	app. 750 hours operation
Filtering 5 µm	app. 1,000 hours operation

Continuous operation of P1V-A standard motors, with lubrication

Oil volume	1 drop oil/Nm ³
Filtering 40 µm	app. 1,000 hours operation
Filtering 5 µm	app. 2,000 hours operation

Continuous lubrication-free operation of P1V-A motors equipped with hard vanes (option "C")

Filtering 40 µm	app. 750 hours operation
Filtering 5 µm	app. 1,000 hours operation

Please refer to page 39 for service kits.

Choice of air motor, general

The motor to be used should be selected by starting with the torque needed at a specific spindle speed. In other words, to choose the right motor, you have to know the required speed and torque. Since maximum power is reached at half the motor's free speed, the motor should be chosen so that the point aimed at is as close as possible to the maximum power of the motor.

The design principle of the motor means that higher torque is generated when it is braked, which tends to increase the speed, etc. This means that the motor has a kind of speed self-regulation function built in.

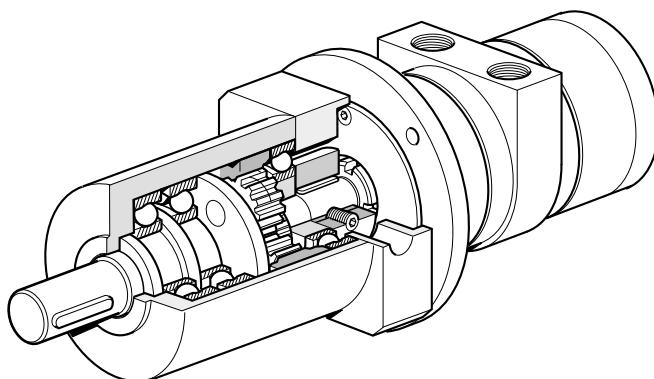

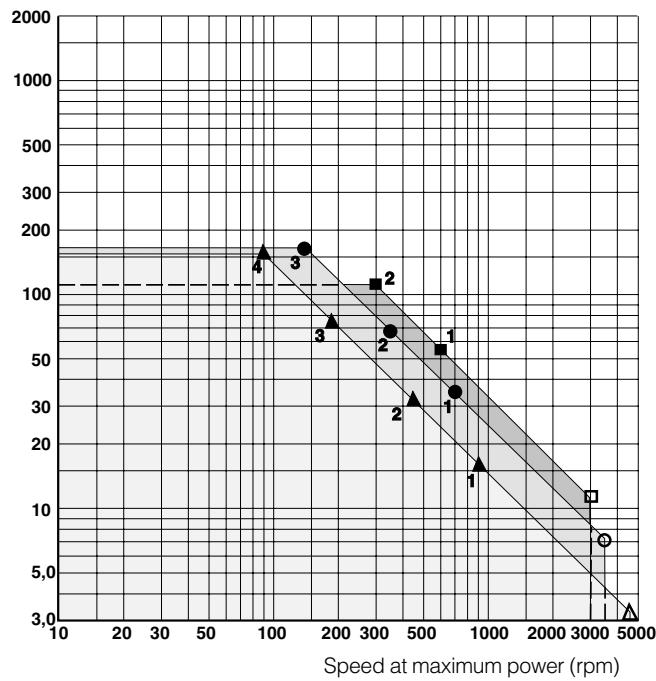

Use the following graph to choose the correct motor size and the correct type of gear as appropriate. The graph contains the points for the maximum torque of each motor at maximum power. Put in your point on the graph and select a marked point above and to the right of the point you need.

Then check the characteristic graph of each motor to find more accurate technical data. Always select a motor where the data required is in the grey field. Also use the correction diagram to see what it would mean to use different air supply pressures with the motor.

Tip: Select a motor which is slightly too fast and powerful, regulate its speed and torque with a pressure regulator and/or restriction to achieve the optimum working point.

Choice of motors with planetary gears

Torque at maximum power (Nm)

Planetary gears are characterised by high efficiency, low moment of inertia and can offer high gear ratios. The output shaft is always in the centre of the gearbox. Small installation dimensions relative to the torque provided. The gears are lubricated by grease, which means that it can be installed in all conceivable positions.

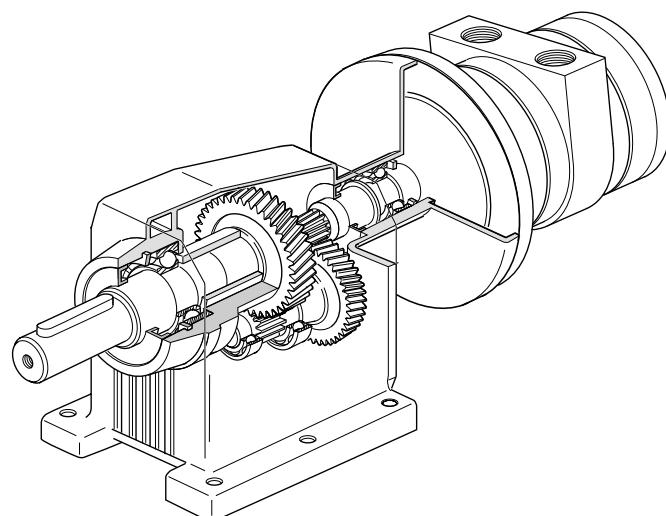

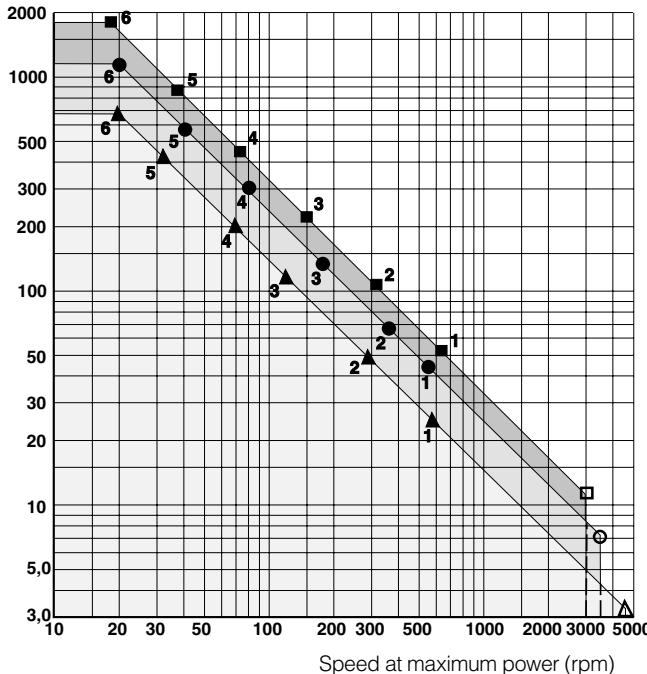

- Small installation dimensions
- Free installation position
- Simple flange installation
- Low weight
- Output shaft in centre
- High efficiency

- 2 P1V-A360B0048, please refer to page 16

Choice of motors with helical gears

Torque at maximum power (Nm)

Helical gears are characterised by high efficiency. Several reduction stages permit relatively high gear ratios. Central output shaft and simple installation with flange or foot.

Oil-bath gearboxes mean that the installation position must be decided in advance. The installation position determines the volume of oil in the gearbox and location of oil filling and drain plugs.

- High efficiency
- Simple flange or foot installation
- Relatively low price

- Installation position must be chosen in advance
- Higher weight than planetary or worm drive gears.

Installation, flange mounting

Please refer to page 18

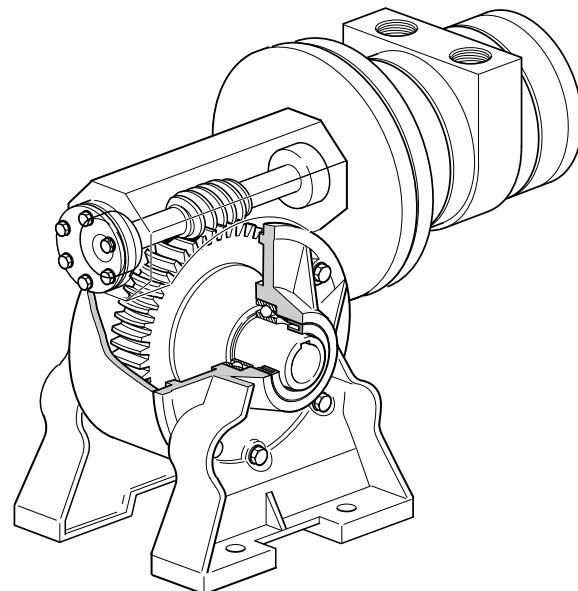

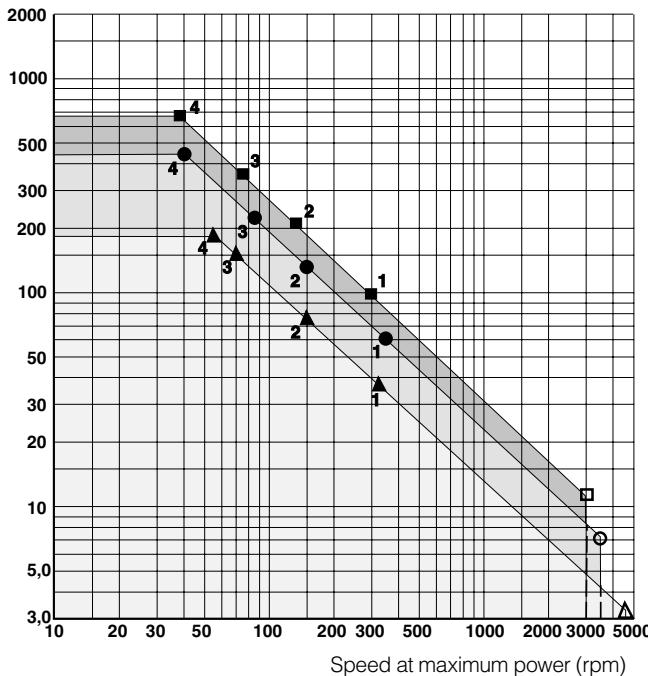

Installation, foot mounting

Please refer to page 19

Choice of motors with worm gears

Torque at maximum power (Nm)

Worm gears are characterised by relatively simple technical construction, with a worm and pinion. This can give a large gear ratio and small dimensions. The efficiency of a worm drive gear is considerably lower than for planetary or helical gears. The design principle of worm drive gears makes them self-locking at higher gear ratios (the output shaft is "locked").

The output shaft comes out at an angle of 90° to the motor spindle. Installation is simple, with a flange on the left or right side, or with a foot. The gearbox is equipped as standard with a hollow output shaft with a key slot. Loose shafts with key can put the output shaft on the right, left, or on both sides.

Oil-bath gearboxes mean that the installation position must be decided in advance. The installation position determines the volume of oil in the gearbox and location of oil filling and drain plugs.

- Low weight in relation to gear ratio
- Non-reversible at high gear ratios
- Relatively low price

- Relatively low efficiency
- Installation position must be decided in advance
- Output shaft at 90° to motor spindle

Technical data

Working pressure	Max 7 bar
Working temperature	-30 °C to +100 °C
Medium	40 µm filtered air with or without oil mist

Design data**Basic motor**

- Robust design with few components
- Spring loaded vanes as standard give good starting and low speed characteristics
- Keyed output shaft
- Reversible operation

Planetary gear

- Precision made gears with efficiency over 95%
- Sealed, permanently grease lubrication gives free installation position
- Compact installation and low weight
- Central output shaft

Helical gear

- Two versions available, with flange or foot
- High efficiency, 90 to 95%
- Oil-bath gearboxes mean that the installation position must be decided in advance. The installation position determines the volume of oil in the gearbox and location of oil filling and drain plugs.

Worm gear

- Available in three versions, for installation with left-hand flange, right-hand flange or foot mounting.
- Compact size and low weight
- Self-locking in higher ratios
- Output shaft at 90° angle to motor spindle
- Hollow output shaft with key slot. Single-ended or "through" twin shaft as options.
- Oil-bath gearboxes mean that the installation position must be decided in advance. The installation position determines the volume of oil in the gearbox and location of oil filling and drain plugs.

Table and diagram data

Note!

- specify installation position in the order no. as in the illustrations below.

Example: P1V-A160F0066B3

Self-locking

Dynamic self-locking means that the force acting on the output shaft of the gear can not turn the gear further when the air motor is stopped. Dynamic self-locking is only possible when the gear ratio is high, and at low speeds. None of our worm drive gears are completely self-locking in dynamic conditions.

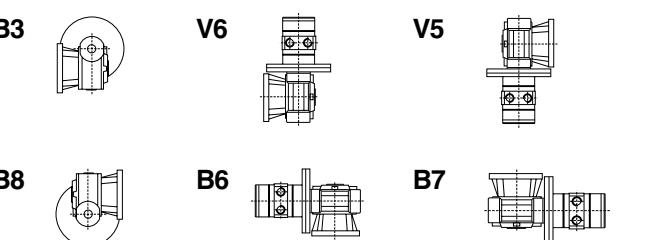

Static self-locking means that the force acting on the output shaft of the gear can not begin to turn the shaft.

When loads with considerable momentum are driven, it is necessary to have a braking time sufficient to stop the gearbox from being overloaded. It is extremely important that the maximum permitted torque is not exceeded.

Tip: Braking of the air motor can be arranged by either slowly restricting the air supply to the motor until it is completely shut off, or by slowly reducing the supply pressure to zero.

Types of Self-locking

1. Static, not self-locking
2. Static, self-locking - quicker return under vibration - not dynamically self-locking
3. Static, self-locking - return only possible under vibration - good dynamic self-locking

Torque and power graphs, please refer to pages 20-21

Permitted shaft loadings, please refer to page 38

Dimensions, please refer to pages 33

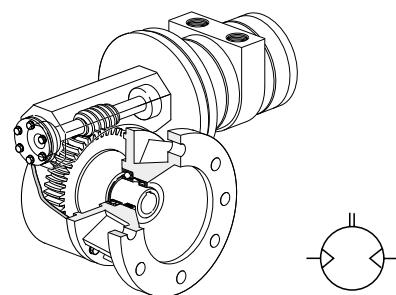

NOTE!

As standard, the motor has a hollow shaft with key slot. Single-ended and double-ended shafts with keys are available as accessories, please refer to page 25.

Important!

Since it is practically impossible to guarantee total self-locking, an external brake must be used to guarantee that vibration can not cause an output shaft to move.

NOTE!

Please refer to the table on page 25 for suitable motors with worm drive gears.

Permitted shaft loadings

Basic motors

Max permitted load on output shaft for basic motors (based on 10,000,000 revolutions of the output shaft, with 90% probable service life for ball bearings).

	F_{ax} N	F_{rad} N	a mm
P1V-A160A0900	600	1000	15
P1V-A260A0700	700	1400	20
P1V-A360A0600	900	1900	25

F_{rad} = Radial loading (N)

F_{ax} = Axial loading (N)

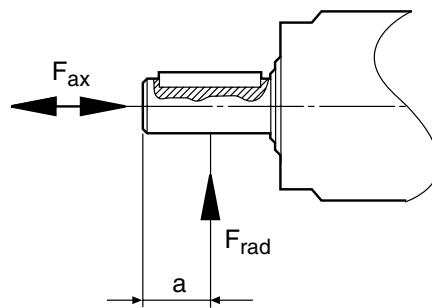

Fig. 1: Loading on output shaft.

Motors with planetary gears

The following calculations should be used to determine the loading on the output shaft bearing, if a service life of 10,000,000 revolutions of the output shaft is to be obtained with 90% probability.

$$F_{ax} = \max 0,24 \times F_{rad}$$

$$M = \pm F_{ax} \times r \pm F_{rad} \times (X + K)$$

Where M and K are found in the table below

	M Nm	K N
P1V-A160B120	2651	0,031
P1V-A160B060	2651	0,031
P1V-A160B019	7385	0,040
P1V-A160B010	7385	0,040
P1V-A260B120	2651	0,031
P1V-A260B060	2651	0,031
P1V-A260B019	7385	0,040
P1V-A360B096	7385	0,040
P1V-A360B048	7385	0,040

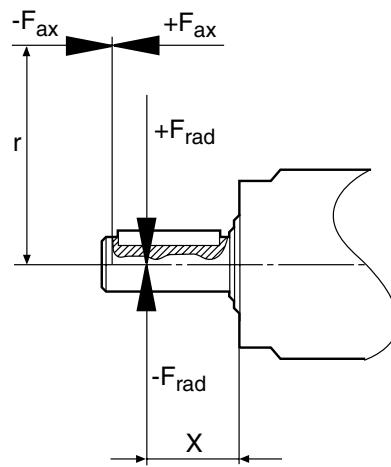

Fig 2: Load and braking torque on output shaft of planetary gear

M Max. torque loading on output shaft (Nm)

r Distance from centre of output shaft to axial load (m)

X Distance from collar to radial load (m)

F_{rad} Radial loading (N)

F_{ax} Axial loading (N)

Motors with helical gear or worm gear

Radial forces

Depending on the application, the drive shaft of the gearbox can be subjected to various radial forces, which can be calculated as follows:

$$F_{rad} = 2000 \times M \times K_r / d$$

F_{rad}	Radial force (N)
M	Torque (Nm)
d	Diameter of wheel, pulley, sprocket or gear wheel (mm)
$K_r = 1$	Sprocket constant
$K_r = 1.25$	Gear wheel constant
$K_r = 1.5 - 2.5$	Vee-belt pulley constant

Depending on the point of application of the force (please refer to the adjacent figure), the following two cases are found:

- The force is applied to the centre of the output shaft, as in figure 3. This value can be read off on the table below, where consideration must be given to the following:

$$F_{radc} \leq F_{rt}$$

- The force is applied at a distance x, as in figure 4. This value can be calculated as follows:

$$F_{radx} = F_{rt} \times a / (b + X) \text{ gäller för } L/2 < X < c$$

F_{rt}	Permissible radial force on centre of output-shaft (N)
a	Gear constant
b	Gear constant
c	Gear constant
X	Distance from shoulder on shaft to point of application of force (mm)

All values are found in the table below.
The following should be considered, however:

$$F_{radc} \leq F_{radx}$$
